The cross-platform audio plug-ins presented here largely simplify the creation and playback of surround sound productions by providing user-friendly access to Ambisonic techniques taken from the most recent research. Hereby, sound designers and composers, the essential end users, can easily employ the newest ways to create, manipulate, and play back Ambisonic recordings in various spatial resolutions. Additionally, the multichannel plug-in suite provides frequently-used equalization features such as levels, delays, and convolution filters to an arbitrary number of channels within one Digital Audio Workstation. The plug-in suite has already been successfully employed in several performances with various sphe- rical playback facilities, in the technical support of computer musicians, and in the production of Ambisonic surround recordings.

Introduction
Spatial audio has not only been a hot research topic but an integral part of cinema sound for many years. The new generation of cinema sound technologies include loudspeakers on different elevation levels thus allowing for the playback of full peripherec surround content. While in private homes such extensive loudspeaker installations are still rare a major amount of music and movies is nowadays consumed through head phones. This work addresses this topic by not only providing monitoring of surround sound over loudspeakers but also through headphones.

For several years research institutions have been experimenting with loudspeaker arrays in two- and three-dimensional setups. Many individual software solutions were developed that support the creation of content for these loudspeaker arrangements. While most Digital Audio Workstations (DAWs) provide tools to produce for standard surround setups such as 5.1 only, more extensive loudspeaker setups (eg. Fig. 4) clearly require tools for a more flexible channel routing. To overcome the limitation of DAWs, most tools for spatial audio were developed in graphical programming environments, such as Pure Data and MaxMSP, which basically have no restriction concerning the number of channels and offer quick development and maintenance cycles. However, not only is the integration of such external spatialization toolboxes into a DAW challenging for the developer, these toolboxes are often also challenging to use for non-experts. Audio channels and control data have to be sent between the applications and complex routing scenarios need to be re-established everytime. This frequently causes difficulties when sharing projects and due to the low of the ability to render audio tracks offline.

Digital Audio Workstation

In the cross-platform audio plug-ins presented here an extensible mixing/editing and export functionality is added multichannel amb and Ambisonic ambis plug-ins:

- + Encoders (Panner) for mono/stereo...
- + Spatial effects (Reverb, Widing...)...
- + Multichannel Metering
- + Ambisonic Format Converters
- + Ambisonic Formatters
- + Decoders for Loudspeakers
- + Decoders for Headphones
- + Ambisonic Delay and Gain

This plug-in suite is meant to get rid of the above-mentioned difficulties. It has been developed as an open source project in C++ using the JUCE framework which supports building audio plug-ins in all major formats and standalone audio applications for Windows, MacOS and Linux. Currently the software is provided as VST and standalone binaries for Windows and MacOS.

Using flexible DAWs such as Reaper or Ardour allows for a single software controlling the entire production cycle starting from panning the source signals, mixing microphone array recordings until decoding the playback signals and adjusting the loudspeaker signals.

Ambisonics
Ambisonics can be used to create spatial audio productions for circular or spherical loudspeaker arrangements. In contrast to channel-based standards in surround sound such as 5.1, it offers flexibility regarding the loudspeaker setup around the listening area. This makes the production stage largely independent of the loudspeaker arrangement. Furthermore, Ambisonic content can be recorded using its classical and new main microphone array technology. Ambisonics is based on the expansion of the surround signal into spherical harmonics up to the order $N$ which defines the angular resolution. A full peripherec (3D) Ambisonic signal set of order $N$ results in $(3N + 1)$ channels. The maximum Ambisonic order $N$ for all amb猪插-ins can be defined as compile time and is only limited by the maximum number of channels per track of the host.

Conclusion
A suite of cross-platform Ambisonic and multichannel effect plug-ins has been presented. The software allows to use extensive multichannel microphone and loudspeaker arrays within Digital Audio Workstations. By keeping the whole production within one host, the editing and offline rendering functionality of DAWs can be used to efficiently create and share immersive surround productions.

The software has already been successfully used by professionals and students for the production of 3D sound surround and formed an integral part of the concert setup in various venues.
